Abstract

Let Ω be a bounded simply connected domain in the complex plane, \mathbb{C} . Let N be a neighborhood of $\partial\Omega$, let p be fixed, $1 < p < \infty$, and let \hat{u} be a positive weak solution to the p Laplace equation in $\Omega \cap N$. Assume that \hat{u} has zero boundary values on $\partial\Omega$ in the Sobolev sense and extend \hat{u} to $N \setminus \Omega$ by putting $\hat{u} \equiv 0$ on $N \setminus \Omega$. Then there exists a positive finite Borel measure $\hat{\mu}$ on \mathbb{C} with support contained in $\partial\Omega$ and such that

$$\int |\nabla \hat{u}|^{p-2} \langle \nabla \hat{u}, \nabla \phi \rangle dA = - \int \phi d\hat{\mu}$$

whenever $\phi \in C_0^\infty(N)$. If $p = 2$ and if \hat{u} is the Green function for Ω with pole at $x \in \Omega \setminus \bar{N}$ then the measure $\hat{\mu}$ coincides with harmonic measure at x , $\omega = \omega^x$, associated to the Laplace equation. In this paper we continue the studies in [BL05], [L06] by establishing new results, in simply connected domains, concerning the Hausdorff dimension of the support of the measure $\hat{\mu}$. In particular, we prove results, for $1 < p < \infty$, $p \neq 2$, reminiscent of the famous result of Makarov [Mak85] concerning the Hausdorff dimension of the support of harmonic measure in simply connected domains.

1 Introduction

Let $\Omega \subset \mathbf{R}^n$ be a bounded domain and recall that the continuous Dirichlet problem for Laplace's equation in Ω can be stated as follows. Given a continuous function f on $\partial\Omega$, find a harmonic function u in Ω which is continuous in $\bar{\Omega}$, with $u = f$ on $\partial\Omega$. Although such a classical solution may not exist, it follows from a method of Perron-Wiener-Brelot that there is a unique bounded harmonic function u with continuous boundary values equal to f , outside a set of capacity zero (logarithmic capacity for $n = 2$ and Newtonian capacity for $n > 2$). The maximum principle and Riesz representation theorem yield, for each $x \in \Omega$, the existence of a Borel measure ω^x with $\omega^x(\partial\Omega) = 1$, and

$$u(x) = \int_{\partial\Omega} f(y) d\omega^x(y) \quad \text{whenever } x \in \Omega.$$

Then, $\omega = \omega^x$ is referred to as the harmonic measure at x associated with the Laplace operator.

Let also $g = g(\cdot) = g(\cdot, x)$ be the Green function for Ω with pole at $x \in \Omega$ and extend g to $\mathbf{R}^n \setminus \Omega$ by putting $g \equiv 0$ on $\mathbf{R}^n \setminus \Omega$. Then ω is the Riesz measure associated to g in the sense that

$$\int \langle \nabla g, \nabla \phi \rangle dx = - \int \phi d\omega \quad \text{whenever } \phi \in C_0^\infty(\mathbf{R}^n \setminus \{x\}).$$

We define the Hausdorff dimension of ω , denoted $\text{H-dim } \omega$, by

$$\text{H-dim } \omega = \inf\{\alpha : \text{there exists } E \text{ Borel } \subset \partial\Omega \text{ with } H^\alpha(E) = 0 \text{ and } \omega(E) = \omega(\partial\Omega)\},$$

where $H^\alpha(E)$, for $\alpha \in \mathbf{R}_+$, is the α -dimensional Hausdorff measure of E defined below. In the past twenty years a number of remarkable results concerning $\text{H-dim } \omega$ have been established in planar domains, $\Omega \subset \mathbf{R}^2$. In particular, Carleson [C85] showed that $\text{H-dim } \omega = 1$ when $\partial\Omega$ is a snowflake and that $\text{H-dim } \omega \leq 1$ for any self similar Cantor set. Later Makarov [Mak85] proved that $\text{H-dim } \omega = 1$ for any simply connected domain in the plane. Furthermore, Jones and Wolff [JW88] proved that $\text{H-dim } \omega \leq 1$ whenever $\Omega \subset \mathbf{R}^2$ and ω exists and Wolff [W93] strengthened [JW88] by showing that ω is concentrated on a set of finite H^1 -measure. We also mention results of Batakis [Ba96], Kaufmann-Wu [KW85], and Volberg [V93] who showed, for certain fractal domains and domains whose complements are Cantor sets, that

$$\text{Hausdorff dimension of } \partial\Omega = \inf\{\alpha : H^\alpha(\partial\Omega) = 0\} > \text{H-dim } \omega.$$

Finally we note that higher dimensional results for the dimension of harmonic measure can be found in [Bo87], [W95], and [LVV05].

In [BL05] the first author, together with Bennewitz, started the study of the dimension of a measure, here referred to as p harmonic measure, associated with a positive p harmonic function which vanishes on the boundary of certain domains in the plane. The study in [BL05] was continued in [L06]. Let \mathbb{C} denote the complex plane and let dA be Lebesgue measure on \mathbb{C} . If $O \subset \mathbb{C}$ is open and $1 \leq q \leq \infty$, let $W^{1,q}(O)$ be the space of equivalence classes of functions \hat{u} with distributional gradient $\nabla \hat{u} = (\hat{u}_x, \hat{u}_y)$, both of which are q th power integrable on O . Let

$$\|\hat{u}\|_{1,q} = \|\hat{u}\|_q + \|\nabla \hat{u}\|_q$$

be the norm in $W^{1,q}(O)$ where $\|\cdot\|_q$ denotes the usual Lebesgue q norm in O . Let $C_0^\infty(O)$ be infinitely differentiable functions with compact support in O and let $W_0^{1,q}(O)$ be the closure of $C_0^\infty(O)$ in the norm of $W^{1,q}(O)$. Let $\Omega \subset \mathbb{C}$ be a simply connected domain and suppose that the boundary of Ω , $\partial\Omega$, is bounded and non empty. Let N be a neighborhood of $\partial\Omega$, p fixed, $1 < p < \infty$, and let \hat{u} be a positive weak solution to the p Laplace equation in $\Omega \cap N$. That is, $\hat{u} \in W^{1,p}(\Omega \cap N)$ and

$$\int |\nabla \hat{u}|^{p-2} \langle \nabla \hat{u}, \nabla \theta \rangle dA = 0 \quad (1.1)$$

whenever $\theta \in W_0^{1,p}(\Omega \cap N)$. Observe that if \hat{u} is smooth and $\nabla \hat{u} \neq 0$ in $\Omega \cap N$, then $\nabla \cdot (|\nabla \hat{u}|^{p-2} \nabla \hat{u}) \equiv 0$, in the classical sense, where $\nabla \cdot$ denotes divergence. We assume that \hat{u} has zero boundary values on $\partial\Omega$ in the Sobolev sense. More specifically if $\zeta \in C_0^\infty(N)$, then $\hat{u} \zeta \in W_0^{1,p}(\Omega \cap N)$. Extend \hat{u} to $N \setminus \Omega$ by putting $\hat{u} \equiv 0$ on $N \setminus \Omega$. Then $\hat{u} \in W^{1,p}(N)$ and it follows from (1.1), as in [HKM93], that there exists a positive finite Borel measure $\hat{\mu}$ on \mathbb{C} with support contained in $\partial\Omega$ and the property that

$$\int |\nabla \hat{u}|^{p-2} \langle \nabla \hat{u}, \nabla \phi \rangle dA = - \int \phi d\hat{\mu} \quad (1.2)$$

whenever $\phi \in C_0^\infty(N)$. We note that if $\partial\Omega$ is smooth enough, then $d\hat{\mu} = |\nabla \hat{u}|^{p-1} dH^1|_{\partial\Omega}$. Note that if $p = 2$ and if \hat{u} is the Green function for Ω with pole at $x \in \Omega$ then the measure $\hat{\mu}$ coincides with harmonic measure at x , $\omega = \omega^x$, introduced above. We refer to $\hat{\mu}$ as the p harmonic measure associated to \hat{u} . In [BL05], [L06] the Hausdorff dimension of the p harmonic measure $\hat{\mu}$ is studied for general p , $1 < p < \infty$, and to state results from [BL05], [L06] we next properly introduce the notions of Hausdorff measure and Hausdorff dimension. In particular, let points in the complex plan be denoted by $z = x + iy$ and put $B(z, r) = \{w \in \mathbb{C} : |w - z| < r\}$ whenever $z \in \mathbb{C}$ and $r > 0$. Let $d(E, F)$ denote the distance between the sets $E, F \subset \mathbb{C}$. If $\lambda > 0$ is a positive function on $(0, r_0)$ with $\lim_{r \rightarrow 0} \lambda(r) = 0$ define H^λ Hausdorff measure on \mathbb{C} as follows: For fixed $0 < \delta < r_0$ and $E \subseteq \mathbb{R}^2$, let $L(\delta) = \{B(z_i, r_i)\}$ be such that $E \subseteq \bigcup B(z_i, r_i)$ and $0 < r_i < \delta$, $i = 1, 2, \dots$. Set

$$\phi_\delta^\lambda(E) = \inf_{L(\delta)} \sum \lambda(r_i).$$

Then

$$H^\lambda(E) = \lim_{\delta \rightarrow 0} \phi_\delta^\lambda(E).$$

In case $\lambda(r) = r^\alpha$ we write H^α for H^λ . We now define the Hausdorff dimension of the measure $\hat{\mu}$ introduced in (1.2) as

$$\text{H-dim } \hat{\mu} = \inf\{\alpha : \text{there exists } E \text{ Borel } \subset \partial\Omega \text{ with } H^\alpha(E) = 0 \text{ and } \hat{\mu}(E) = \hat{\mu}(\partial\Omega)\}.$$

In [BL05] the first author, together with Bennewitz, proved the following theorem.

Theorem A. *Let $\hat{u}, \hat{\mu}$, be as in (1.1), (1.2). If $\partial\Omega$ is a quasicircle, then $H\text{-dim } \hat{\mu} \leq 1$ for $2 \leq p < \infty$, while $H\text{-dim } \hat{\mu} \geq 1$ for $1 < p \leq 2$. Moreover, if $\partial\Omega$ is the von Koch snowflake then strict inequality holds for $H\text{-dim } \hat{\mu}$.*

In [L06] the results in [BL05] were improved at the expense of assuming more about $\partial\Omega$. In particular, we refer to [L06] for the definition of a k quasi-circle. The following theorem is proved in [L06]

Theorem B. *Given $p, 1 < p < \infty, p \neq 2$, there exists $k_0(p) > 0$ such that if $\partial\Omega$ is a k quasi-circle and $0 < k < k_0(p)$, then*

- (a) $\hat{\mu}$ is concentrated on a set of σ finite H^1 measure when $p > 2$.
- (b) There exists $A = A(p), 0 < A(p) < \infty$, such that if $1 < p < 2$, then $\hat{\mu}$ is absolutely continuous with respect to Hausdorff measure defined relative to $\tilde{\lambda}$ where

$$\tilde{\lambda}(r) = r \exp[A\sqrt{\log 1/r \log \log 1/r}], 0 < r < 10^{-6}.$$

We note that Makarov in [Mak85] proved Theorem B for harmonic measure $\omega, p = 2$, when Ω is simply connected. Moreover, in this case it suffices to take $A = 6\sqrt{(\sqrt{24} - 3)/5}$, see [HK07]. In this paper we continue the studies in [BL05] and [L06] and we prove the following theorem.

Theorem 1. *Given $p, 1 < p < \infty, p \neq 2$, let $\hat{u}, \hat{\mu}$ be as in (1.1), (1.2), and suppose Ω is simply connected. Put*

$$\lambda(r) = r \exp[A\sqrt{\log 1/r \log \log 1/r}], 0 < r < 10^{-6}.$$

Then the following is true.

- (a) *If $p > 2$, there exists $A = A(p) \leq -1$ such that $\hat{\mu}$ is concentrated on a set of σ finite H^λ measure.*
- (b) *If $1 < p < 2$, there exists $A = A(p) \geq 1$, such that $\hat{\mu}$ is absolutely continuous with respect to H^λ .*

Note that Theorem 1 and the definition of H-dim $\hat{\mu}$ imply the following corollary.

Corollary 1. *Given $p, 1 < p < \infty, p \neq 2$, let $\hat{u}, \hat{\mu}$ be as in (1.1), (1.2), and suppose Ω is simply connected. Then $H\text{-dim } \hat{\mu} \leq 1$ for $2 \leq p < \infty$, while $H\text{-dim } \hat{\mu} \geq 1$ for $1 < p \leq 2$.*

In Lemma 2.4, stated below, we first show that it is enough to to prove Theorem 1 for a specific p harmonic function \hat{u} satisfying the hypotheses. Thus, we choose $z_0 \in \Omega$ and let u be the p capacity functions for $D = \Omega \setminus \overline{B}(z_0, d(z_0, \partial\Omega)/2)$. Then u is p harmonic in D with continuous boundary values, $u \equiv 0$ on $\partial\Omega$ and $u \equiv 1$ on $\partial B(z_0, d(z_0, \partial\Omega)/2)$. Furthermore, to prove Theorem 1, we build on the tools and techniques developed in [BL05]. In particular, as noted in [BL05, sec. 7, Closing Remarks, problem 5], given the tools in [BL05] the main difficulty in establishing Theorem 1 is to prove the following result.

Theorem 2. *Given $p, 1 < p < \infty, p \neq 2$, let u, D be as above. There exists $c_1 \geq 1$, depending only on p , such that*

$$c_1^{-1} \frac{u(z)}{d(z, \partial\Omega)} \leq |\nabla u(z)| \leq c_1 \frac{u(z)}{d(z, \partial\Omega)}, \text{ whenever } z \in D.$$

In fact, most of our effort in this paper is devoted to proving Theorem 2. Armed with Theorem 2 we then use arguments from [BL05] and additional measure-theoretic arguments to prove Theorem 1. To further appreciate and understand the importance of the type of estimate we establish in Theorem 2, we note that this type of estimate is also crucial in the recent work by the first and second author on the boundary behaviour, regularity and free boundary regularity for p harmonic functions, $p \neq 2, 1 < p < \infty$, in domains in $\mathbf{R}^n, n \geq 2$, which are Lipschitz or which are well approximated by Lipschitz domains in the Hausdorff distance sense, see [LN07, LN, LN08a, LN08b]. Moreover, Theorem 2 seems likely to be an important step when trying to solve several problems for p harmonic functions and p harmonic measure, in planar simply-connected domains previously only studied in the case $p = 2$, i.e., for harmonic functions and harmonic measure. In particular, we refer to [BL05, sec. 7, Closing Remarks] and [L06, Closing Remarks] for discussions of open problems.

The rest of the paper is organized as follows. In section 2 we list some basic local results for a positive p harmonic function vanishing on a portion of $\partial\Omega$. In section 3 we use these results to prove Theorem 1 under the assumption that Theorem 2 is valid. In sections 4 and 5 we then prove Theorem 2.

Finally the first author would like to thank Michel Zinsmeister for some helpful comments regarding the proof of (4.16).

2 Basic Estimates.

In the sequel c will denote a positive constant ≥ 1 (not necessarily the same at each occurrence), which may depend only on p , unless otherwise stated. In general, $c(a_1, \dots, a_n)$ denotes a positive constant ≥ 1 , which may depend only on p, a_1, \dots, a_n , not necessarily the same at each occurrence. C will denote an absolute constant. $A \approx B$ means that A/B is bounded above and below by positive constants depending only on p . In this section, we will always assume that Ω is a bounded simply connected domain, $0 < r < \text{diam } \partial\Omega$ and $w \in \partial\Omega$. We begin by stating some interior and boundary estimates for \tilde{u} , a positive weak solution to the p Laplacian in $B(w, 4r) \cap \Omega$ with $\tilde{u} \equiv 0$ in the Sobolev sense on $\partial\Omega \cap B(w, 4r)$. That is, $\tilde{u} \in W^{1,p}(B(w, 4r) \cap \Omega)$ and (1.1) holds whenever $\theta \in W_0^{1,p}(B(w, 4r) \cap \Omega)$. Also $\zeta \tilde{u} \in W_0^{1,p}(B(w, 4r) \cap \Omega)$ whenever $\zeta \in C_0^\infty(B(w, 4r))$. Extend \tilde{u} to $B(w, 4r)$ by putting $\tilde{u} \equiv 0$ on $B(w, 4r) \setminus \Omega$. Then there exists a locally finite positive Borel measure $\tilde{\mu}$ with support $\subset B(w, 4r) \cap \partial\Omega$ and for which (1.2) holds with \hat{u} replaced by \tilde{u} and $\phi \in C_0^\infty(B(w, 4r))$. Let $\max_{B(z,s)} \tilde{u}, \min_{B(z,s)} \tilde{u}$ be the essential supremum and infimum of \tilde{u} on $B(z, s)$ whenever $B(z, s) \subset B(w, 4r)$. For references to proofs of Lemmas 2.1 - 2.3 (see [BL05]).

Lemma 2.1. Fix $p, 1 < p < \infty$, and let Ω, w, r, \tilde{u} , be as above. Then

$$c^{-1} r^{p-2} \int_{B(w, r/2)} |\nabla \tilde{u}|^p dx \leq \max_{B(w, r)} \tilde{u}^p \leq c r^{-2} \int_{B(w, 2r)} \tilde{u}^p dx.$$

If $B(z, 2s) \subset \Omega$, then

$$\max_{B(z, s)} \tilde{u} \leq c \min_{B(z, s)} \tilde{u}.$$

Lemma 2.2. Let $p, \Omega, w, r, \tilde{u}$, be as in Lemma 2.1. Then there exists $\alpha = \alpha(p) \in (0, 1)$ such that \tilde{u} has a Hölder α continuous representative in $B(w, r)$ (also denoted \tilde{u}). Moreover if $x, y \in B(w, r)$ then

$$|\tilde{u}(x) - \tilde{u}(y)| \leq c(|x - y|/r)^\alpha \max_{B(w, 2r)} \tilde{u}.$$

Lemma 2.3. Let $p, \Omega, w, r, \tilde{u}$, be as in Lemma 2.1 and let $\tilde{\mu}$ be the measure associated with \tilde{u} as in (1.2). Then there exists c such that

$$c^{-1} r^{p-2} \tilde{\mu}[B(w, r/2)] \leq \max_{B(w, r)} \tilde{u}^{p-1} \leq c r^{p-2} \tilde{\mu}[B(w, 2r)].$$

Using Lemma 2.3 we prove,

Lemma 2.4. Fix $p, 1 < p < \infty$, and let \hat{u} be the positive p harmonic function in Theorem 1. Also, let u be the p capacitary function for $D = \Omega \setminus \bar{B}(z_0, d(z_0, \partial\Omega)/2)$, defined below Corollary 1, and let $\mu, \hat{\mu}$, be the measures corresponding to u, \hat{u} , respectively. Then $\mu, \hat{\mu}$ are mutually absolutely continuous. In particular, Theorem 1 is valid for $\hat{\mu}$ if and only if it is valid for μ .

Proof: We note that if $\nu \neq 0$ is a finite Borel measure on \mathbb{C} with compact support, then

$$\nu(\mathbb{C} \setminus \Gamma) = 0 \text{ where } \Gamma = \left\{ z \in \text{supp } \nu : \liminf_{t \rightarrow 0} \frac{\nu(B(z, 100t))}{\nu(B(z, t))} \leq 10^9 \right\} \quad (2.5)$$

Indeed otherwise, there exists a Borel set $\Lambda \subset \mathbb{C}$ with $\nu(\Lambda) > 0$ and the property that if $z \in \Lambda$, then there exists $t_0(z) > 0$ for which

$$\nu(B(z, t)) \leq 10^{-8} \nu(B(z, 100t)) \text{ for } 0 < t < t_0(z). \quad (2.6)$$

Iterating (2.6) it follows that

$$\lim_{t \rightarrow 0} \frac{\nu(B(z, t))}{t^3} = 0 \text{ whenever } z \in \Lambda. \quad (2.7)$$

Since $H^3(\mathbb{C}) = 0$, we deduce from (2.7) that $\nu(\Lambda) = 0$, which is a contradiction. Thus (2.5) is true.

Now suppose that $\mu, \hat{\mu}$ are as in Lemma 2.4. Let N_1 be a neighborhood of $\partial\Omega$ with

$$\partial\Omega \subset N_1 \subset \bar{N}_1 \subset N.$$

Then from compactness and continuity of \hat{u}, u , there exists $\hat{M} < \infty$ such that

$$u \leq \hat{M}\hat{u} \leq \hat{M}^2 u \quad (2.8)$$

on $\Omega \cap \partial N_1$. From (2.8) and the boundary maximum principle for p harmonic functions we conclude that (2.8) holds in $\Omega \cap N_1$. In view of (2.8) and Lemma 2.3 we see there exists $\hat{r} > 0$, and a constant $b < \infty$, such that

$$\mu(B(w, s)) \leq b\hat{\mu}(B(w, 2s)) \leq b^2\mu(B(w, 4s)) \quad (2.9)$$

whenever $w \in \partial\Omega$ and $0 < s \leq \hat{r}$. We also note from Lemma 2.3 that $\text{supp } \mu = \text{supp } \hat{\mu} = \partial\Omega$.

The proof of Lemma 2.4 is by contradiction. Let $E \subset \partial\Omega$ be a Borel set with $\hat{\mu}(E) = 0$. If $\mu(E) > 0$, then from properties of Borel measures, and with Γ as in (2.5) with $\nu = \mu$, we see there exists a compact set K with

$$K \subset E \cap \Gamma \text{ and } \mu(K) > 0. \quad (2.10)$$

Given $\epsilon > 0$ there also exists an open set O with

$$E \subset O \text{ and } \hat{\mu}(O) < \epsilon. \quad (2.11)$$

Moreover, we may suppose for each $z \in K$ that there is a $\rho = \rho(z)$ with $0 < \rho(z) < \hat{r}/1000$, $\bar{B}(z, 100\rho(z)) \subset O$, and

$$\mu(B(z, 100\rho)) \leq 10^{10}\mu(B(z, \rho)). \quad (2.12)$$

Applying Vitali's covering theorem we then get $\{B(z_i, r_i)\}$ with $z_i \in \partial\Omega, 0 < 100r_i < \hat{r}$ and the property that

$$\begin{aligned} (a) \quad & (2.12) \text{ holds with } \rho = r_i \text{ for each } i, \\ (b) \quad & K \subset \bigcup_i B(z_i, 100r_i) \subset O, \\ (c) \quad & B(z_i, 10r_i) \cap B(z_j, 10r_j) = \emptyset \text{ when } i \neq j. \end{aligned} \quad (2.13)$$

Using (2.9) and (2.11) - (2.13), it follows that

$$\begin{aligned} \mu(K) &\leq \mu[\bigcup_i B(z_i, 100r_i)] \leq \sum_i \mu[B(z_i, 100r_i)] \leq 10^{10} \sum_i \mu[B(z_i, r_i)] \\ &\leq 10^{10} b \sum_i \hat{\mu}[B(z_i, 10r_i)] \leq 10^{10} b \hat{\mu}(O) \leq 10^{10} b \epsilon. \end{aligned} \quad (2.14)$$

Since ϵ is arbitrary we conclude that $\mu(K) = 0$, which contradicts (2.10). Thus μ is absolutely continuous with respect to $\hat{\mu}$. Interchanging the roles of $\mu, \hat{\mu}$ we also get that $\hat{\mu}$ is absolutely continuous with respect to μ . Thus Lemma 2.4 is true. \square

3 Proof of Theorem 1 (assuming Theorem 2).

From Lemma 2.4 we see that it suffices to prove Theorem 1 with $\hat{u}, \hat{\mu}$, replaced by u, μ . In this section we prove Theorem 1 for u under the assumption that Theorem 2 is correct. Given Theorem 2 we can follow closely the argument in [BL05] from (6.9) on. However, our argument is necessarily somewhat more complicated, as in [BL05] we used the fact that μ was a doubling measure, which is not necessarily true when Ω is simply connected. We claim that it suffices to prove Theorem 1 when

$$z_0 = 0 \text{ and } d(z_0, \partial\Omega) = 2. \quad (3.1)$$

Indeed, let $\tau = d(z_0, \partial\Omega)/2$ and put $T(z) = z_0 + \tau z$. If $u'(z) = u(T(z))$ for $z \in D$, then since the p Laplacian is invariant under translations, rotations, dilations, it follows that u' is p harmonic in $T^{-1}(D)$. Let μ' be the measure corresponding to u' . Then from (1.2) it follows easily that

$$\mu'(E) = \tau^{p-2} \mu(T(E)) \text{ whenever } E \subset \mathbb{R}^n \text{ is a Borel set.}$$

This equality clearly implies that $\text{H-dim } \mu' = \text{H-dim } \mu$. Thus we may assume that (3.1) holds. Then $B(0, 2) \subset \Omega$ and $D = \Omega \setminus \bar{B}(0, 1)$.

Using Theorem 2 we have, for some $c = c(p) \geq 1$, that

$$c^{-1} \frac{u(z)}{d(z, \partial\Omega)} \leq |\nabla u(z)| \leq c \frac{u(z)}{d(z, \partial\Omega)} \text{ whenever } z \in D. \quad (3.2)$$

Next set

$$v(x) = \begin{cases} \max(\log |\nabla u(x)|, 0) & \text{when } 1 < p < 2 \\ \max(-\log |\nabla u(x)|, 0) & \text{when } p > 2. \end{cases}$$

Then in [BL05] it is shown that

$$\int_{\{x: u(x)=t\}} |\nabla u|^{p-1} \exp \left[\frac{w^2}{2c_+ \log(1/t)} \right] dH^1 x \leq 2c_+ \quad (3.3)$$

for some $c^+ \geq 1$. In [BL05], c^+ depends on k, p , but only because the constant in (3.2) depends on k, p . So, given Theorem 2, $c^+ = c^+(p)$ in (3.3). Next let

$$\xi(t) = 2\sqrt{c_+ \log(1/t) \log \log(1/t)} \text{ for } 0 < t < 10^{-6},$$

$$F(t) = \{x : u(x) = t \text{ and } v(x) \geq \xi(t)\}.$$

Then from (3.3) and weak type estimates we deduce

$$\int_{F(t)} |\nabla u|^{p-1} dH^1 x \leq 2c_+ [\log(1/t)]^{-2}. \quad (3.4)$$

Next for A fixed with $|A|$ large, we define λ as in Theorem 1. Let $a = \frac{|A|}{2\sqrt{c^+}}$ and note that

$$\lambda(r) = \begin{cases} r e^{a\xi(r)} & \text{when } 1 < p < 2, \\ r e^{-a\xi(r)} & \text{when } p > 2. \end{cases} \quad (3.5)$$

To prove Theorem 1 when either $1 < p < 2$ or $p > 2$, we initially allow a to vary but will later fix it as a constant depending only on p , satisfying several conditions. Fix $p, 1 < p < 2$, and let $K \subset \partial\Omega$ be a Borel set with $H^\lambda(K) = 0$. Let K_1 be the subset of all $z \in K$ with

$$\limsup_{r \rightarrow 0} \frac{\mu(B(z, r))}{\lambda(r)} < \infty.$$

Then from the definition of λ and a covering argument (see [Mat95, sec 6.9]), it is easily shown that $\mu(K_1) = 0$. Thus to prove $\mu(K) = 0$, it suffices to show $\mu(E) = 0$ when E is Borel and is equal μ almost everywhere to the set of all points in $\partial\Omega$ for which

$$\limsup_{r \rightarrow 0} \frac{\mu(B(z, r))}{\lambda(r)} = \infty. \quad (3.6)$$

Let G be the set of all z where (3.6) holds. Given $0 < r_0 < 10^{-100}$, we first show for each $z \in G$ that there exists $s = s(z), 0 < s/100 < r_0$, such that

$$\mu(B(z, 100s)) \leq 10^9 \mu(B(z, s)) \text{ and } \lambda(100s) \leq \mu(B(z, s)). \quad (3.7)$$

In fact let $s \in (0, r_0)$ be the first point starting from r_0 where

$$\frac{\mu(B(z, s))}{\lambda(s)} \geq 10^{20} \min \left\{ \frac{\mu(B(z, r_0))}{\lambda(r_0)}, 1 \right\}.$$

From (3.6) we see that s exists. Using $\lambda(100r) \leq 200\lambda(r), 0 < r < r_0/100$, it is also easily checked that (3.7) holds. From (3.7) and Vitali again, we get $\{B(z_i, r_i)\}$ with $z_i \in G, 0 < 100r_i < r_0$, and the property that

$$\begin{aligned} (a) \quad & (3.7) \text{ holds with } z = z_i, s = r_i, \text{ for each } i, \\ (b) \quad & G \subset \bigcup_i B(z_i, 100r_i) \\ (c) \quad & B(z_i, 10r_i) \cap B(z_j, 10r_j) = \emptyset \text{ when } i \neq j. \end{aligned} \quad (3.8)$$

Let $t_m = 2^{-m}$ for $m = 1, 2, \dots$. Given i , we claim there exists $w_i \in B(z_i, 5r_i)$ and $m = m(i)$ with

$$\begin{aligned} (\alpha) \quad & u(w_i) = t_m \text{ and } d(w_i, \partial\Omega) \approx r_i \\ (\beta) \quad & \mu[B(z_i, 10r_i)]/r_i \approx [u(w_i)/d(w_i, \partial\Omega)]^{p-1} \approx |\nabla u(w)|^{p-1} \\ & \text{whenever } w \in B(w_i, d(w_i, \partial\Omega)/2). \end{aligned} \quad (3.9)$$

In (3.9) all proportionality constants depend only on p . To prove (3.9) choose $\zeta_i \in \partial B(z_i, 2r_i)$ with $u(\zeta_i) = \max_{\bar{B}(z_i, 2r_i)} u$. Then $d(\zeta_i, \partial\Omega) \approx r_i$, since otherwise, it would follow from Lemma 2.2 that $u(\zeta_i)$ is small in comparison to $\max_{\bar{B}(z_i, 5r_i)} u$. However from (3.8) (a) and Lemma 2.3, these two maximums are proportional with constants depending only on p . Thus $d(\zeta_i, \partial\Omega) \approx r_i$. Using this fact, (3.2), (3.8) (a), and Lemma 2.3, once again we get (3.9) (β) with w_i replaced by ζ_i . If $t_m \leq u(\zeta_i) < t_{m-1}$ we let w_i be the first point on the line segment connecting ζ_i to a point in

$\partial\Omega \cap \partial B(\zeta_i, d(\zeta_i, \partial\Omega))$ where $u = t_m$. From our construction, Harnack's inequality, and Lemma 2.2 we see that (3.9) is true.

Using (3.8), (3.9), we deduce for $1 < p < 2$ that

$$v(z) = \log |\nabla u(z)| \geq a \xi(100r_i)/\tilde{c} \text{ on } B(w_i, d(w_i, \partial\Omega)/2) \quad (3.10)$$

where a is as in (3.5). Next we note that

$$H^1[B(w_i, d(w_i, \partial\Omega)/2) \cap \{z : u(z) = t_m\}] \geq d(w_i, \partial\Omega)/2 \quad (3.11)$$

as we see from the maximum principle for p harmonic functions, a connectivity argument and basic geometry. Also, we can use (3.8) (a) to estimate t_m below in terms of r_i and Lemma 2.2 to estimate t_m above in terms of r_i . Doing this we find for some $\beta = \beta(p)$, $0 < \beta < 1$, $\bar{c} = \bar{c}(p)$, that

$$r_i \leq \bar{c} t_m^\beta \leq \bar{c}^2 r_i^{\beta^2}. \quad (3.12)$$

Using (3.8)-(3.12) we conclude, for a large enough, that

$$\mu[B(z_i, 10r_i)] \leq c \int_{F(t_m) \cap B(z_i, 10r_i)} |\nabla u|^{p-1} dH^1. \quad (3.13)$$

Using (3.8), (3.12), (3.13), and (3.4) it follows for c large enough that

$$\begin{aligned} \mu(G) &\leq \mu\left(\bigcup_i B(z_i, 100r_i)\right) \leq 10^9 \sum_i \mu[B(z_i, 10r_i)] \\ &\leq c \sum_{m=m_0}^{\infty} \int_{F(t_m)} |\nabla u|^{p-1} dH^1 x \leq c^2 \sum_{m=m_0}^{\infty} m^{-2} \leq c^3 m_0^{-1} \end{aligned} \quad (3.14)$$

where $2^{-m_0\beta} = \bar{c} r_0^{\beta^2}$. Since r_0 can be arbitrarily small we see from (3.14) that $\mu(G) = 0$. This equality and the remark above (3.6) yield $\mu(K) = 0$. Hence μ is absolutely continuous with respect to H^λ and Theorem 1 is true for $1 < p < 2$.

Finally to prove Theorem 1 for $p > 2$, we show there exists a Borel set $\hat{K} \subset \partial\Omega$ such that

$$\mu(\hat{K}) = \mu(\partial\Omega) \text{ and } \hat{K} \text{ has } \sigma \text{ finite } H^\lambda \text{ measure.} \quad (3.15)$$

In fact let \hat{K} be the set of all $z \in \partial\Omega$ with

$$\limsup_{r \rightarrow 0} \frac{\mu(B(z, r))}{\lambda(r)} > 0. \quad (3.16)$$

Let \hat{K}_n be the subset of \hat{K} where the above lim sup is greater than $1/n$. Then from the definition of λ and a Vitali covering type argument (see [Mat95, ch 2]) it follows easily that

$$H^\lambda(\hat{K}_n) \leq 100n\mu(\hat{K}_n).$$

Since $\hat{K} = \cup_n \hat{K}_n$ we conclude that \hat{K} is σ finite with respect to H^λ measure. Thus to prove (3.15) it suffices to show $\mu(\hat{G}) = 0$ where \hat{G} is equal to the set of all points in $\partial\Omega$ for which

$$\lim_{r \rightarrow 0} \frac{\mu(B(z, r))}{\lambda(r)} = 0. \quad (3.17)$$

Given $0 < r_0 < 10^{-100}$ we argue as in the proof of (2.5) to deduce for each $z \in \hat{G}$ the existence of $s = s(z), 0 < s/100 < r_0$, such that

$$\mu(B(z, 100s)) \leq 10^9 \mu(B(z, s)) \text{ and } \lambda(s) \geq \mu(B(z, 100s)). \quad (3.18)$$

Using (3.18) and once again applying Vitali's covering lemma we get $\{B(z_i, r_i)\}$ with $z_i \in \hat{G}, 0 < 100r_i < r_0$, and the property that

$$\begin{aligned} (a) \quad & (3.18) \text{ holds with } z = z_i, s = r_i \text{ for each } i, \\ (b) \quad & \hat{G} \subset \bigcup_i B(z_i, 100r_i), \\ (c) \quad & B(z_i, 10r_i) \cap B(z_j, 10r_j) = \emptyset \text{ when } i \neq j. \end{aligned} \quad (3.19)$$

Let Θ be the set of all indexes, i , for which $\mu(B(z_i, 100r_i)) \geq r_i^3$ and let Θ_1 be the indexes for which this inequality is false. Arguing as in (3.14) we obtain

$$\mu(\hat{G}) \leq \bigcup_{i \in \Theta} \mu(B(z_i, 100r_i)) + \sum_{i \in \Theta_1} r_i^3 \leq 10^9 \bigcup_{i \in \Theta} \mu(B(z_i, 10r_i)) + 100r_0(H^2(\Omega) + 1). \quad (3.20)$$

If $i \in \Theta$, we can repeat the argument after (3.8) to get (3.9). (3.9) and (3.8) (a) imply (3.10) for $w = -\log |\nabla u|$. Also since $i \in \Theta$ we can use (3.9) to estimate t_m from below in terms of r_i and once again use Lemma 2.2 to estimate t_m from above in terms of r_i . Thus (3.12) also holds for some β, \bar{c} depending only on p . (3.10) - (3.12) imply (3.13) for a (as in (3.5)) suitably large. In view of (3.20), (3.13), and (3.4) we have

$$\begin{aligned} \mu(\hat{G}) - 100r_0(H^2(\Omega) + 1) &\leq \mu\left(\bigcup_i B(z_i, 100r_i)\right) \leq 10^9 \sum_{i \in \Theta} \mu[B(z_i, 10r_i)] \\ &\leq c \sum_{m=m_0}^{\infty} \int_{F(t_m)} |\nabla u|^{p-1} dH^1 x \leq c^2 \sum_{m=m_0}^{\infty} m^{-2} \leq c^3 m_0^{-1} \end{aligned} \quad (3.21)$$

where $2^{-m_0\beta} = \bar{c} r_0^{\beta^2}$. Since r_0 can be arbitrarily small we conclude first from (3.21) that $\mu(\hat{G}) = 0$ and thereupon that (3.15) is valid. Hence μ is concentrated on a set of σ finite H^λ measure when $p > 2$. The proof of Theorem 1 is now complete given that Theorem 2 is true. \square

4 Preliminary Reductions for Theorem 2.

Let u be the p capacity function for $D = \Omega \setminus B(z_0, d(z_0, \partial\Omega)/2)$. We extend u to \mathbb{C} by putting $u \equiv 1$ on $\bar{B}(z_0, d(z_0, \partial\Omega)/2)$ and $u \equiv 0$ in $\mathbb{C} \setminus \Omega$. We shall need some more basic properties of u . Again references for proofs can be found in [BL05].

Lemma 4.1. *If $z = x + iy, i = \sqrt{-1}, x, y \in \mathbb{R}$, then $u_z = (1/2)(u_x - iu_y)$ is a quasi-regular mapping of D and $\log |\nabla u|$ is a weak solution to a linear elliptic PDE in divergence form in D . Moreover, positive weak solutions to this PDE in $B(\zeta, r) \subset D$ satisfy the Harnack inequality*

$$\max_{B(\zeta, r/2)} h \leq \tilde{c} \min_{B(\zeta, r/2)} h$$

where \tilde{c} depends only on p .

Lemma 4.2. *u is real-analytic in D , $\nabla u \neq 0$ in D , and ∇u has a Hölder continuous extension to a neighborhood of $\partial B(z_0, d(z_0, \partial\Omega)/2)$. Moreover, there are constants $\beta, 0 < \beta < 1$, and $\hat{c} \geq 1$, depending only on p , such that*

$$|\nabla u(z) - \nabla u(w)| \leq \hat{c} \left(\frac{|z-w|}{d(z, \partial\Omega)} \right)^\beta \max_{B(z, d(z, \partial\Omega)/2)} |\nabla u| \leq \hat{c}^2 \left(\frac{|z-w|}{d(z, \partial\Omega)} \right)^\beta \frac{u(z)}{d(z, \partial\Omega)}$$

whenever $w \in D \cap B(z, d(z, \partial\Omega)/2)$. Finally

$$\hat{c} |\nabla u(w)| \geq \frac{u(w)}{d(w, \partial\Omega)} \text{ for } w \in D \cap B(z_0, 3d(z_0, \partial\Omega)/4).$$

Using Lemma 4.2 we see that Theorem 2 is true when $z \in D \cap B(z_0, 3d(z_0, \partial\Omega)/4)$. Thus it is enough to prove Theorem 2 with $z = z_1$ for

$$z_1 \in D \setminus B(z_0, 3d(z_0, \partial\Omega)/4). \quad (4.3)$$

Recall the definition of the hyperbolic distance ρ_Ω for a simply connected domain Ω (see [GM05]). Then $\rho_\Omega(z_1, z_2)$, $z_1, z_2 \in \Omega$, is comparable to the quasi-hyperbolic distance

$$Q_\Omega(z_1, z_2) := \inf_\gamma \int_\gamma \frac{|dz|}{d(z, \partial\Omega)}$$

where the infimum is taken over all the paths $\gamma \subset \Omega$ connecting z_1 to z_2 . More specifically,

$$\rho_\Omega \leq Q_\Omega \leq 4\rho_\Omega \quad (4.4)$$

as follows from the Koebe estimates

$$\frac{1}{4} |f'(z)|(1 - |z|^2) \leq d(f(z), \partial\Omega) \leq |f'(z)|(1 - |z|^2), \quad z \in B(0, 1), \quad (4.5)$$

whenever $f : B(0, 1) \rightarrow \Omega$ is a conformal map, (see Theorem I.4.3 in [GM05]). In the following we will often use the following distortion estimate, which also follows from Koebe's Theorem, (see (I.4.17) in [GM05]), for conformal maps $f : B(0, 1) \rightarrow \mathbb{C}$. For $z_1, z_2 \in D$,

$$\rho_\Omega(z_1, z_2) \leq A_1 \implies |f'(f^{-1}(z_2))| \leq A_2 |f'(f^{-1}(z_1))| \quad (4.6)$$

for some constant A_2 depending only on A_1 . Note also that (4.6) implies that $d(z_2, \partial\Omega) \leq A_3 d(z_1, \partial\Omega)$ for some constant A_3 depending only on A_2 . The same holds if f is a conformal mapping of the upper half-plane \mathbb{H} . Our main lemma in the proof of Theorem 2 is the following.

Lemma 4.7. *There is a constant C , depending only on p , such that if z_1 is as in (4.3) then there exists $z^* \in \Omega$ with $u(z^*) = u(z_1)/2$ and $\rho_\Omega(z_1, z^*) \leq C$.*

Assuming for the moment that Lemma 4.7 is proved we get Theorem 2 from the following argument. Let Γ be the hyperbolic geodesic connecting z_1 to z^* . If $\Gamma \cap B(z_0, 5d(z_0, \partial\Omega)/8) = \emptyset$,

we put $\gamma = \Gamma$. Otherwise, $\gamma = \gamma_1 + \gamma_2 + \gamma_3$ where γ_1 is the subarc of Γ joining z_1 to the first point, P_1 , where Γ intersects $\partial B(z_0, 5d(z_0, \partial\Omega)/8)$; γ_2 is the short arc of $\partial B(z_0, 5d(z_0, \partial\Omega)/8)$ joining P_1 to the last point, P_2 , where γ intersects $\partial B(z_0, 5d(z_0, \partial\Omega)/8)$; and finally γ_3 joins P_2 to z^* . Using (4.3)-(4.6), one sees that

$$H^1(\gamma) \leq cd(z_1, \partial\Omega) \text{ and } d(\gamma, \partial\Omega) \geq c^{-1}d(z_1, \partial\Omega), \quad (4.8)$$

where $c = c(p)$. Thus

$$\frac{1}{2}u(z_1) \leq u(z_1) - u(z^*) \leq \int_{\gamma} |\nabla u(z)| |dz| \leq cH^1(\gamma) \max_{\gamma} |\nabla u| \leq Cd(z_1, \partial\Omega) \max_{\gamma} |\nabla u|.$$

So for some $\zeta \in \gamma$,

$$c^* |\nabla u(\zeta)| \geq \frac{u(z_1)}{d(z_1, \partial\Omega)} \quad (4.9)$$

where $c^* \geq 1$ depends only on p . Also from (4.8) we deduce the existence of balls $\{B(w_j, r_j)\}_{j=1}^N$, with $w_j \in \gamma$ and

$$\begin{aligned} (a) \quad & B(w_j, r_j/4) \cap B(w_{j+1}, r_{j+1}/4) \neq \emptyset \text{ for } 1 \leq j \leq N-1, \\ (b) \quad & r_j \approx d(B(w_j, r_j), \partial\Omega) \approx d(z_1, \partial\Omega), \\ (c) \quad & \gamma \subset \bigcup_j B(w_j, r_j/4), \end{aligned} \quad (4.10)$$

where N and proportionality constants depend only on p . Observe from (4.10) and Harnack's inequality applied to u (see Lemma 2.1) that $u(z) \approx u(z_1)$ when $z \in \cup_j B(w_j, r_j)$. In view of Lemma 4.2, (4.10), it follows for some $c = c(p)$ that

$$|\nabla u(z)| \leq cu(z_1)/d(z_1, \partial\Omega) \text{ when } z \in \bigcup_j B(w_j, r_j/2). \quad (4.11)$$

From (4.11) we see that if $c = c(p) \geq 1$ is large enough and

$$h(z) =: \log \left(\frac{cu(z_1)}{d(z_1, \partial\Omega) |\nabla u(z)|} \right) \text{ for } z \in \bigcup_j B(w_j, r_j/2)$$

then $h > 0$ in $\cup_j B(w_j, r_j/2)$. Choose $i, 1 \leq i \leq N$, so that $\zeta \in B(w_i, r_i/4)$. Using (4.9) we have $h(\zeta) \leq c$. Applying the Harnack inequality in Lemma 4.1 to h in $B(w_i, r_i/2)$ we get

$$c |\nabla u| \geq u(z_1)/d(z_1, \partial\Omega) \text{ in } B(w_i, r_i/4). \quad (4.12)$$

From (4.10) we see that the argument leading to (4.12) can be repeated in a chain of balls connecting ζ to z_1 . Doing this and using $N = N(p)$, we get Theorem 2. \square

In the proof of Lemma 4.7 we may assume without loss of generality that $\partial\Omega$ is an analytic Jordan curve, as the constant in this lemma will depend only on p . Indeed, we can approximate Ω by an increasing sequence of analytic Jordan domains $\Omega_n \subset \Omega$, and apply Lemma 4.7 to u_n the p capacitary function for $D_n = \Omega_n \setminus B(z_0, d(z_0, \partial\Omega)/2)$. Doing this and letting $n \rightarrow \infty$, we get Lemma 4.7 for u , since by Lemmas 2.2, 4.2, there are subsequences of $u_n, \nabla u_n$, converging to $u, \nabla u$, respectively, uniformly on compact subsets of Ω .

4.1 Outline of the proof of Lemma 4.7.

To prove Lemma 4.7 It will be useful to transfer the problem to the upper half-plane \mathbb{H} via the Riemann map $f : \mathbb{H} \rightarrow \Omega$ such that $f(i) = z_0$ and $f(a) = z_1$ where $a = is$ for some $0 < s < 1$. We note that f has a continuous extension to $\bar{\mathbb{H}}$, since $\partial\Omega$ is a Jordan curve. We also let $U = u \circ f$, and note that U satisfies a maximum principle and Harnack's inequality. Consider the box

$$Q(a) = \{z = x + iy : |x| \leq s, 0 < y < s\}.$$

We will show that $Q(a)$ can be shifted to a nearby box $\tilde{Q}(a)$ whose boundary in \mathbb{H} we call ξ . It consists of the horizontal segment from $x_1 + is$ to $x_2 + is$, and the vertical segments connecting $x_l + is$ to x_l for $l = 1, 2$. x_1, x_2 , are chosen to satisfy $-s < x_1 < -s/2, s/2 < x_2 < s$. Let $f(x_j) = w_j, j = 1, 2$. $\tilde{Q}(a)$ will be constructed to have several nice properties. In particular, we will prove that $U \leq AU(a)$, on ξ , and hence, by the maximum principle, $U \leq AU(a)$ on $\tilde{Q}(a)$, for some constant A depending only on p . In other words, if we let $\sigma := f(\xi)$ and $\Omega_1 := f(\tilde{Q}(a))$, then we will prove that

$$u \leq Au(z_1) \tag{4.13}$$

on σ and hence in Ω_1 . Moreover, we will prove that

$$H^1(\sigma) \leq C_1 d(z_1, \partial\Omega) \tag{4.14}$$

for some absolute constant C_1 depending only on p . Furthermore, we will establish the existence of $w_0 = f(x_0)$, for some $|x_0| < s/4$, such that $|w_0 - z_1| \leq C_2 d(z_1, \partial\Omega)$ and such that

$$d(w_0, \sigma) \geq d(z_1, \partial\Omega)/C_2 \tag{4.15}$$

where C_2 is an other absolute constant. In addition we will construct a Lipschitz curve $\tau : [0, 1] \rightarrow \Omega_1$ with $\tau(0) = z_1$ and $\tau(1) = w_0$, which satisfies the cigar condition

$$\min\{H^1(\tau[0, t]), H^1(\tau[t, 1])\} \leq C_3 d(\tau(t), \partial\Omega), \tag{4.16}$$

for $0 \leq t \leq 1$ and some absolute constant C_3 .

To briefly outline the construction of τ we note that we construct τ as the image under f of a polygonal path

$$\lambda = \sum_{k=1}^{\infty} \lambda_k \subset \tilde{Q}(a),$$

starting at a and tending to x_0 non-tangentially. The segment $\lambda_k, k = 1, 2, \dots$, joins a_{k-1} to a_k and consists of a horizontal line segment followed by a downward pointing vertical segment. More precisely, fix $\delta, 0 < \delta < 10^{-1000}$ and put $\delta^* = e^{-c^*/\delta}, t_0 = 0, s_0 = s, a_0 = t_0 + is_0 = a$. In our construction we initially allow δ to vary but shall fix δ in (5.3) to be a small positive absolute constant satisfying several conditions. Also, $c^* \geq 1$ is an absolute constant which will be defined in Lemma 4.26. Then λ_1 consists of the horizontal segment from a_0 to $t_1 + is_0$ followed by the vertical segment from $t_1 + is_0$ to $a_1 = t_1 + i\delta^*s_0$. Put $s_1 = \delta^*s_0$. Inductively, if $a_{k-1} = t_{k-1} + is_{k-1}$ has been defined, then λ_k consists of the horizontal line segment joining a_{k-1} to $t_k + is_{k-1}$, followed by the vertical line segment connecting $t_k + is_{k-1}$ to $a_k = t_k + is_k$, where $s_k = \delta^*s_{k-1}$. Moreover the numbers $t_k, k = 1, 2, \dots$, are chosen in such a way that

$$|t_k - t_{k-1}| \leq s_{k-1} \text{ and } \int_0^{s_k} |f'(t_k + i\tau)| d\tau \leq \delta d(f(a_{k-1}), \partial\Omega). \tag{4.17}$$

Existence of (t_k) will be shown in the paragraph after (5.2). Letting $\tau_k = f(\lambda_k)$ and $z_k = f(a_{k-1}), k = 1, 2, \dots$, we note that (4.17) and our construction imply

$$d(z_{k+1}, \partial\Omega) \leq \delta d(z_k, \partial\Omega). \quad (4.18)$$

For $w \in \lambda_k$, (4.6) and our construction give a constant \bar{c} , depending only on δ and p , such that

$$\bar{c}^{-1}|f'(a_{k-1})| \leq |f'(w)| \leq \bar{c}|f'(a_{k-1})| \text{ whenever } w \in \lambda_k.$$

Consequently for some constant $c \geq 1$, depending only on δ and p ,

$$c d(w, \partial\Omega) \geq d(z_k, \partial\Omega) \text{ when } w \in \tau_k \text{ and } H^1(\tau_k) \leq c(\delta)d(z_k, \partial\Omega) \quad (4.19)$$

for $k = 1, 2, 3, \dots$

Putting (4.18) and (4.19) together we see that if $w = \tau(t) \in \tau_k$, then for some $c_+ \geq 1$, depending only on δ and p ,

$$|w - w_0| \leq H^1(\tau[t, 1]) \leq \sum_{j=k}^{\infty} H^1(\tau_j) \leq c_+ d(w, \partial\Omega) \leq c_+^2 \delta^{k-1} d(z_1, \partial\Omega).$$

Using this equality and (4.19) we conclude that τ satisfies the cigar condition in (4.16) with a constant depending only on δ, p .

To show the existence of z^* in Lemma 4.7, we suppose $\delta > 0$ is now fixed as in (5.3) and suppose that λ is parametrized by $[0, 1]$ with $\lambda(0) = a$ and $\lambda(1) = x_0$. Let

$$t^* = \max\{t : U(\lambda(t)) = \frac{1}{2}U(a)\}$$

and put $a^* = \lambda(t^*)$ and $z^* = f(a^*)$. If $\rho = d(w_0, \sigma)$, Then from the definition of Ω_1 above (4.13) we have

$$B(w_0, \rho) \cap \Omega \subset \Omega_1.$$

so from Lemma 2.2 applied to the restriction of u to Ω_1 , (4.13), (4.15), and (4.16) we deduce for some $\tilde{c} = \tilde{c}(p)$ that

$$\frac{1}{2}u(z_1) = u(z^*) \leq \tilde{c} \left(\frac{d(z^*, \partial\Omega)}{\rho} \right)^\alpha \max_{B(w_0, \rho) \cap \Omega} u \leq \tilde{c}^2 A \left(\frac{d(z^*, \partial\Omega)}{d(z_1, \partial\Omega)} \right)^\alpha u(z_1).$$

Thus

$$d(z_1, \partial\Omega) \leq c d(z^*, \partial\Omega) \text{ for some } c = c(p).$$

This inequality and (4.16) imply that there is a chain of $N = N(p)$ balls (as in (4.10)) connecting z_1 to z^* . Using this implication and once again (4.4) we conclude that $\rho_\Omega(z^*, z_1) \leq c$. This completes our outline of the proof of Lemma 4.7.

To finish the proof of Lemma 4.7 we show there exists $\delta > 0, \sigma, \tau, c^*, (\tau_k)_1^\infty$, for which (4.13) - (4.15) and (4.17), are true.

4.2 Several Lemmas.

To set the stage for the proof of (4.13) - (4.15) and (4.17) we shall need several lemmas. To this end define, for $b \in \mathbb{H}$, the interval $I(b) := [\operatorname{Re} b - \operatorname{Im} b, \operatorname{Re} b + \operatorname{Im} b]$.

Lemma 4.20. *There is an absolute constant \hat{C} such that if f is univalent on \mathbb{H} and $b \in \mathbb{H}$, then*

$$\int \int_{\mathbb{H}} \frac{|f'(w)|}{|f(w) - f(b)|} dA(w) \leq \hat{C} \operatorname{Im} b.$$

Proof of Lemma 4.20: The proof is left as an exercise. Hints are provided in problem 21 on page 33 of [GM05], where the case for functions g univalent on $B(0, 1)$ with $\operatorname{Re} g \neq 0$ is discussed. The same arguments give the result for univalent functions g on $B(0, 1)$ with $g(0) = 0$ and then Lemma 4.20 is obtained by applying the result to $g = f \circ M_b$ where $M_b(z) = i \operatorname{Im} b(1 + z)/(1 - z) + \operatorname{Re} b$. \square

Lemma 4.21. *There is a set $E(b) \subset I(b)$ such that for $x \in E(b)$*

$$\int_0^{\operatorname{Im} b} |f'(x + iy)| dy \leq C^* d(f(b), \partial\Omega) \quad (4.22)$$

for some absolute constant C^* , and also

$$H^1(E(b)) \geq (1 - 10^{-100})H^1(I(b)). \quad (4.23)$$

Note that we could achieve Lemma 4.21 by invoking known results in the literature, such as the result in [BB99] related to previous theorems of Beurling and Pommerenke (see [P75], Section 10.3). For completeness we give an alternative proof of Lemma 4.21 based on Lemma 4.20.

Proof of Lemma 4.21: Let ℓ be a large positive integer that will soon be fixed as an absolute number and let

$$T = T(b) = \{z = x + iy : |x| < \operatorname{Im} b : y = \operatorname{Im} b\}$$

be the top of the box $Q(b)$ defined at the beginning of subsection 4.1. Set

$$K = K(b) := \{x \in I(b) : |f(x + it) - f(b)| > 2^\ell |f'(b)| \operatorname{Im} b \text{ for some } 0 < t < \operatorname{Im} b\}.$$

Note that

$$|\partial_y \log |f(z) - f(b)|| \leq \frac{|f'(z)|}{|f(z) - f(b)|}.$$

Also, for z in the top T ,

$$|f(z) - f(b)| \leq 1000 |f'(b)| \operatorname{Im} b.$$

Thus,

$$\int_0^{\operatorname{Im} b} \frac{|f'(x + iy)|}{|f(x + iy) - f(b)|} dy \geq \frac{\ell}{C},$$

whenever $x \in K$. Integrating both sides over K and using Lemma 4.20 we therefore find that

$$H^1(K) \leq C \frac{\text{Im } b}{\ell}. \quad (4.24)$$

Next for we define a function $g(x)$ for $x \in I(b)$ as follows. If $x \in I(b) \setminus K$ we set

$$g(x) := \int_0^{\text{Im } b} |f'(x + iy)| dy$$

and if $x \in K$ then we set $g(x) = 0$. From the definition of K we see that

$$g(x) \leq 2^\ell |f'(b)| \text{Im } b \int_0^{\text{Im } b} \frac{|f'(x + iy)|}{|f(x + iy) - f(b)|} dy$$

whenever $x \in I(b)$. Using this inequality and Integrating over $I(b)$ we find that

$$\int_{I(b)} g(x) dx \leq C 2^\ell |f'(b)| (\text{Im } b)^2 \leq C^2 2^\ell d(f(b), \partial\Omega) \text{Im } b.$$

So from weak-type estimates, if

$$K' := \{x \in I(b) : g(x) > 2^{2\ell} d(f(b), \partial\Omega)\},$$

then

$$H^1(K') \leq C^2 2^{-\ell} \text{Im } b, \quad (4.25)$$

for some absolute constant C . Using (4.24) and (4.25) we can fix ℓ to be a large absolute number so that

$$H^1(K \cup K') < 10^{-100} \text{Im } b.$$

With ℓ thus fixed we put

$$E(b) := I(b) \setminus (K \cup K')$$

and conclude that Lemma 4.21 is valid. \square

Lemma 4.26. *Let b, C^* be as in Lemma 4.21 and put $c^* = 4(C^*)^2$. Given $0 < \delta < 10^{-1000}$, let $\delta_\star = e^{-c^*/\delta}$. Then, whenever $x \in E(b)$ there is an interval $J = J(x)$ centered at x with*

$$2\delta_\star \text{Im } b \leq H^1(J) \leq C\delta^{1/2} \text{Im } b \leq \frac{\text{Im } b}{10000} \quad (4.27)$$

(for some absolute constant C) and a subset $F = F(x) \subset J$ with $H^1(F) \geq (1 - 10^{-100})H^1(J)$ so that

$$\int_0^{\delta_\star \text{Im } b} |f'(t + iy)| dy \leq \delta d(f(b), \partial\Omega) \quad \text{for every } t \in F. \quad (4.28)$$

Proof of Lemma 4.26: Given $x \in E(b)$ put $b' = x + i \operatorname{Im} b$ and let $y_1, 0 < y_1 < \operatorname{Im} b$, be such that

$$d(f(x + iy), \partial\Omega) > \frac{\delta}{C^*} d(f(b), \partial\Omega)$$

for $y_1 < y < \operatorname{Im} b$, but

$$d(f(\hat{b}), \partial\Omega) = \frac{\delta}{C^*} d(f(b), \partial\Omega)$$

where $\hat{b} := x + iy_1$. By (4.4), Lemma 4.21, and conformal invariance of hyperbolic distance,

$$\log \frac{\operatorname{Im} b}{y_1} \leq \rho_{\mathbb{H}}(\hat{b}, b') \leq 4Q_{\Omega}(f(\hat{b}), f(b')) \leq \frac{4C^*}{\delta d(f(b), \partial\Omega)} \int_{y_1}^{\operatorname{Im} b} |f'(x + iy)| dy \leq \frac{4(C^*)^2}{\delta},$$

i.e., $y_1 \geq \delta_* \operatorname{Im} b$. Let $J = I(\hat{b})$ and $F = E(\hat{b})$. Then by Lemma 4.21, $H^1(F) \geq (1 - 10^{-100})H^1(J)$ and for $t \in E(\hat{b})$

$$\int_0^{\delta_* \operatorname{Im} b} |f'(t + iy)| dy \leq C^* d(f(\hat{b}), \partial\Omega) = \delta d(f(b), \partial\Omega).$$

Notice also that,

$$H^1(J) = 2 \operatorname{Im} \hat{b} \geq 2\delta_* \operatorname{Im} b.$$

On the other hand, elementary distortion theorems for univalent functions (see for example [GM05, ch 1, section 4]) and the fact that $\hat{b} \in Q(b)$ yield for some absolute constant $C_+ \geq 1$ that

$$\delta/C^* = \frac{d(f(\hat{b}), \partial\Omega)}{d(f(b), \partial\Omega)} \geq \left(\frac{\operatorname{Im} \hat{b}}{C_+ \operatorname{Im} b} \right)^2.$$

Thus (4.27), (4.28) are valid and the proof of Lemma 4.26 is complete. \square

Lemma 4.29 *Let $b, x \in E(b), J(x), F(x)$, be as in Lemma 4.26 and set $\hat{F} = \bigcup_{x \in E(b)} F(x)$. If $L \subset I(b)$ is an interval with $H^1(L) \geq \frac{\operatorname{Im} b}{100}$, then*

$$H^1(E(b) \cap \hat{F} \cap L) \geq \frac{\operatorname{Im} b}{1000}. \quad (4.30)$$

Moreover, if $\{\tau_1, \tau_2, \dots, \tau_m\}$ is a set of points in $I(b)$, then there exists τ_{m+1} in $E(b) \cap \hat{F} \cap L$ with

$$|f(\tau_{m+1}) - f(\tau_j)| \geq \frac{d(f(b), \partial\Omega)}{10^{10} m^2} \text{ whenever } 1 \leq j \leq m. \quad (4.31)$$

Proof of Lemma 4.29: Given an interval I let λI be the interval with the same center as I and λ times its length. Using Vitali, we see there exists $\{\hat{x}_j\} \subset E(b) \cap \frac{1}{2}L$ and $\{J(\hat{x}_j)\}$ as in Lemma 4.26 such that

$$E(b) \cap \frac{1}{2}L \subset \bigcup_j 4J(\hat{x}_j) \text{ and the intervals } \{J(\hat{x}_j)\} \text{ are pairwise disjoint.}$$

Observe from (4.27) that $J(\hat{x}_j) \subset L$ for each j . From this fact and (4.27) we get

$$\begin{aligned} H^1(\hat{F} \cap L) &\geq \sum_j H^1(\hat{F} \cap J(\hat{x}_j)) \geq (1 - 10^{-100}) \sum_j H^1(J(\hat{x}_j)) \geq \frac{1-10^{-100}}{4} \sum_j H^1(4J(\hat{x}_j)) \\ &\geq \frac{1 - 10^{-100}}{4} H^1(E(b) \cap \frac{1}{2}L) \geq \text{Im } b/900. \end{aligned} \quad (4.32)$$

From (4.32) and (4.23) we conclude that (4.30) is valid. To prove (4.31) observe from (4.30) and the Poisson integral formula for \mathbb{H} that

$$\omega(E(b) \cap \hat{F} \cap L, b) \geq 10^{-4} \quad (4.33)$$

where $\omega(\cdot, b)$ denotes harmonic measure on \mathbb{H} relative to b . Let

$$r = \sup_{x \in E(b) \cap \hat{F} \cap L} \min\{|f(x) - f(\tau_j)|, 1 \leq j \leq m\}.$$

Then

$$f(E(b) \cap \hat{F} \cap L) \subset \bigcup_{j=1}^m \bar{B}(f(\tau_j), r).$$

Using this fact, (4.33), and invariance of harmonic measure under f , it follows that

$$10^{-4} \leq \sum_{j=1}^m \tilde{\omega}(\bar{B}(f(\tau_j), r), f(b)) \quad (4.34)$$

where $\tilde{\omega}(\cdot, f(b))$ denotes harmonic measure in Ω relative to $f(b)$. Finally we note from the Beurling projection theorem (see [GM05, ch 3, Corollary 9.3]) that for each j ,

$$\tilde{\omega}(\bar{B}(f(\tau_j), r), f(b)) \leq (4/\pi) \left(\frac{r}{d(f(b), \partial\Omega)} \right)^{1/2}.$$

Using this inequality in (4.34) we conclude that (4.31) is true. The proof of Lemma 4.29 is now complete. \square

5 Proof of Theorem 2.

5.1 Proof of (4.14) and (4.15)

Using Lemma 4.29 with $b = a = is$, we deduce for given $\delta, 0 < \delta < 10^{-1000}$, the existence of $x_1, x_2, x_3 \in E(a)$ with $-s < x_1 < -s/2$, $-\frac{1}{8}s < x_3 < \frac{1}{8}s$, and $\frac{1}{2}s < x_2 < s$, such that

$$\int_0^{\delta_* s} |f'(x_j + iy)| dy \leq \delta d(f(a), \partial\Omega) \text{ for } 1 \leq j \leq 3, \quad (5.1)$$

$$\min\{|f(x_1) - f(x_3)|, |f(x_2) - f(x_3)|\} \geq 10^{-11} d(f(a), \partial\Omega). \quad (5.2)$$

As earlier we let $\tilde{Q}(a)$ be the shifted box whose boundary in \mathbb{H}, ξ , consists of the horizontal line segment from $x_1 + is$ to $x_2 + is$, and the vertical line segments from x_j to $x_j + is$, for $j = 1, 2$. Also we put $\sigma = f(\xi)$ and note from $x_j \in E(a), j = 1, 2$, that (4.14) is valid. Moreover, we let $w_i = f(x_i)$ for $i \in \{1, 2, 3\}$. To construct τ as defined after (4.15), we put $t_1 = x_3$ and continue as outlined above (4.17). In general if $a_{k-1} = t_{k-1} + is_{k-1}$, we choose $t_k \in E(a_{k-1})$ so that (4.17) holds with $s_k = \delta_* s_{k-1}$. This choice is possible thanks to Lemma 4.29. With λ now defined note from the argument following (4.17) that $x_0 = \lim_{t \rightarrow 1} \lambda(t)$ exists, $|x_0| < 1/4$, and that $\tau = f(\lambda)$ satisfies the cigar condition in (4.16) for $t \in [0, 1)$. If $w_0 = \tau(1)$, then using (4.17), (4.18), we see that

$$|w_3 - w_0| \leq \hat{C} \delta d(z_1, \partial\Omega)$$

for some absolute constant \hat{C} . From this inequality and (5.2), it follows that if

$$\delta = \min(10^{-12} \hat{C}^{-1}, 10^{-1000}), \quad (5.3)$$

then

$$\min\{|w_0 - w_j|, j = 1, 2\} \geq 10^{-12} d(z_1, \partial\Omega). \quad (5.4)$$

With δ now fixed, we see from (5.1) that the part of σ , say σ_1 , corresponding to the vertical line segments from x_j to $x_j + i\delta_* s$, $j = 1, 2$, satisfies

$$d(\sigma_1, w_0) \geq 10^{-13} d(z_1, \partial\Omega). \quad (5.5)$$

Using (4.4) we also get

$$d(\sigma \setminus \sigma_1, \partial\Omega) \geq C^{-1} d(z_1, \partial\Omega) \quad (5.6)$$

for some absolute constant C . Combining (5.5), (5.6), we obtain (4.15).

5.2 Proof of (4.13)

The proof of (4.13) is by contradiction. Suppose $u > Au(z_1)$ on σ . We shall obtain a contradiction if $A = A(p)$ is suitably large. Our argument is based on a recurrence type scheme often attributed to Carleson - Domar, see [C62], [D57], in the complex world, and to Caffarelli et. al., see [CFMS81], in the PDE world (see also [AS05] for references). Given the shifted box $\tilde{Q}(a)$ we let $b_{j,1} = x_j + i\delta_* \text{Im } a, j = 1, 2$, and note that $b_{j,1}, j = 1, 2$, are points on the vertical sides of $\tilde{Q}(a)$. These points will spawn two new boxes $\tilde{Q}(b_{j,1}), j = 1, 2$, which in turn will each spawn two more new boxes, and so on. Without loss of generality, we focus on $\tilde{Q}(b_{1,1})$. This box is constructed in the same way as $\tilde{Q}(a)$ and we also construct, using Lemma 4.29 once again, a polygonal path $\lambda_{1,1}$ from $b_{1,1}$ to some point $x_{1,1} \in I(b_{1,1})$, so that $\lambda_{1,1}$ is defined relative to $b_{1,1}$ in the same way that λ was defined relative to a . There is only one caveat. Namely, the path $\lambda_{1,1}$ is required to be contained in the half-plane $\{\text{Re } z < \text{Re } b_{1,1}\}$, i.e., to stay entirely to the left of $b_{1,1}$. This extra caveat is easily achieved in view of Lemma 4.29. $\lambda_{2,1}$ with endpoints, $b_{2,1}, x_{2,1}$ is constructed similarly, to lie in $\{\text{Re } z > \text{Re } b_{2,1}\}$ (see Picture 1).

Next, using the Harnack inequality we see that there exists Λ such that

$$u(f(z)) \leq \Lambda u(f(a)) \text{ whenever } z = x + iy \in \xi, y \geq \delta_* \text{Im } a. \quad (5.7)$$

Figure 1: Domar-type recursion construction

In particular, from Harnack's inequality for u and the fact that δ is now fixed in (5.3), it is clear that Λ in (5.7) can be chosen to depend only on p , and hence can also be used in further iterations.

By (5.7), the fact that $A > \Lambda$ and the maximum principle, we see that there exists a point $z \in \lambda_{1,1} \cup \lambda_{2,1}$ such that $U(z) > AU(a)$. This is the reason why the paths $\lambda_{j,1}$ are constructed outside the original box $\tilde{Q}(a)$. First suppose $z \in \lambda_{1,1}$. The larger the constant A , the closer z will be to \mathbb{R} . More precisely, if $A > \Lambda^k$ then $\text{Im } z \leq \delta_*^k \text{Im } a$, as we see from (5.7) and inequalities analogous to (4.17)-(4.19). Arguing as in the display below (4.19), we find that

$$|f(z) - f(x_{1,1})| \leq C\delta^{k-1}d(f(b_{1,1}), \partial\Omega).$$

The argument now is similar to the argument showing the existence of z^* at the end of subsection 4.1. Let $\xi_{1,1}$ be the boundary of $\tilde{Q}(b_{1,1})$ which is in \mathbb{H} and let $\sigma_{1,1} = f(\xi_{1,1})$. Set $\rho_{1,1} := d(w_{0,1}, \sigma_{1,1})$, where $w_{0,1} = f(x_{1,1})$. Then

$$B(w_{0,1}, \rho_{1,1}) \cap \Omega \subset f(\tilde{Q}(b_{1,1})).$$

So, by Lemma 2.2,

$$u(f(z)) \leq C\delta^{\alpha k} \max_{\tilde{Q}(b_{1,1})} u \circ f.$$

Choose k , depending only on p , to be the least positive integer such that

$$C\delta^{\alpha k} < \Lambda^{-1}.$$

This choice of k determines A (say $A = 2\Lambda^k$) which therefore also depends only on p (since δ is fixed in (5.3)). With this choice of A we have

$$\max_{\xi_{1,1}} U > \Lambda U(z) > \Lambda AU(a). \quad (5.8)$$

Since $U(b_{1,1}) \leq \Lambda U(a)$ we see from (5.8) that we can now repeat the above argument with $\tilde{Q}(b_{1,1})$ playing the role of $\tilde{Q}(a)$. That is, we find $b_{1,2}$ on the vertical sides of $\tilde{Q}(b_{1,1})$ with $\text{Im } b_{1,2} = \delta_*^2 \text{Im } a$ and a box $\tilde{Q}(b_{1,2})$ with boundary $\xi_{1,2}$ such that

$$\max_{\xi_{1,2}} U > \Lambda^2 AU(a) \geq AU(b_{1,2}).$$

Continuing by induction we get a contradiction because $U = 0$ continuously on \mathbb{R} . If $z \in \lambda_{2,1}$, we get a contradiction by the same argument. Thus, there exists $A = A(p) \geq 1$ for which (4.13) holds. The proof of Theorem 2 is now complete. \square
